Summary

First, we take a look at a summary of the data.

- There are missing values in the AGE, YOJ, and CAR_AGE columns that must be imputed.
- There are multiple categorical variables that will have to be encoded (MSTATUS, HOME_VAL, SEX, EDUCATION, JOB, CAR_USE, RED_CAR, REVOKED, URBANICITY)

Distributions

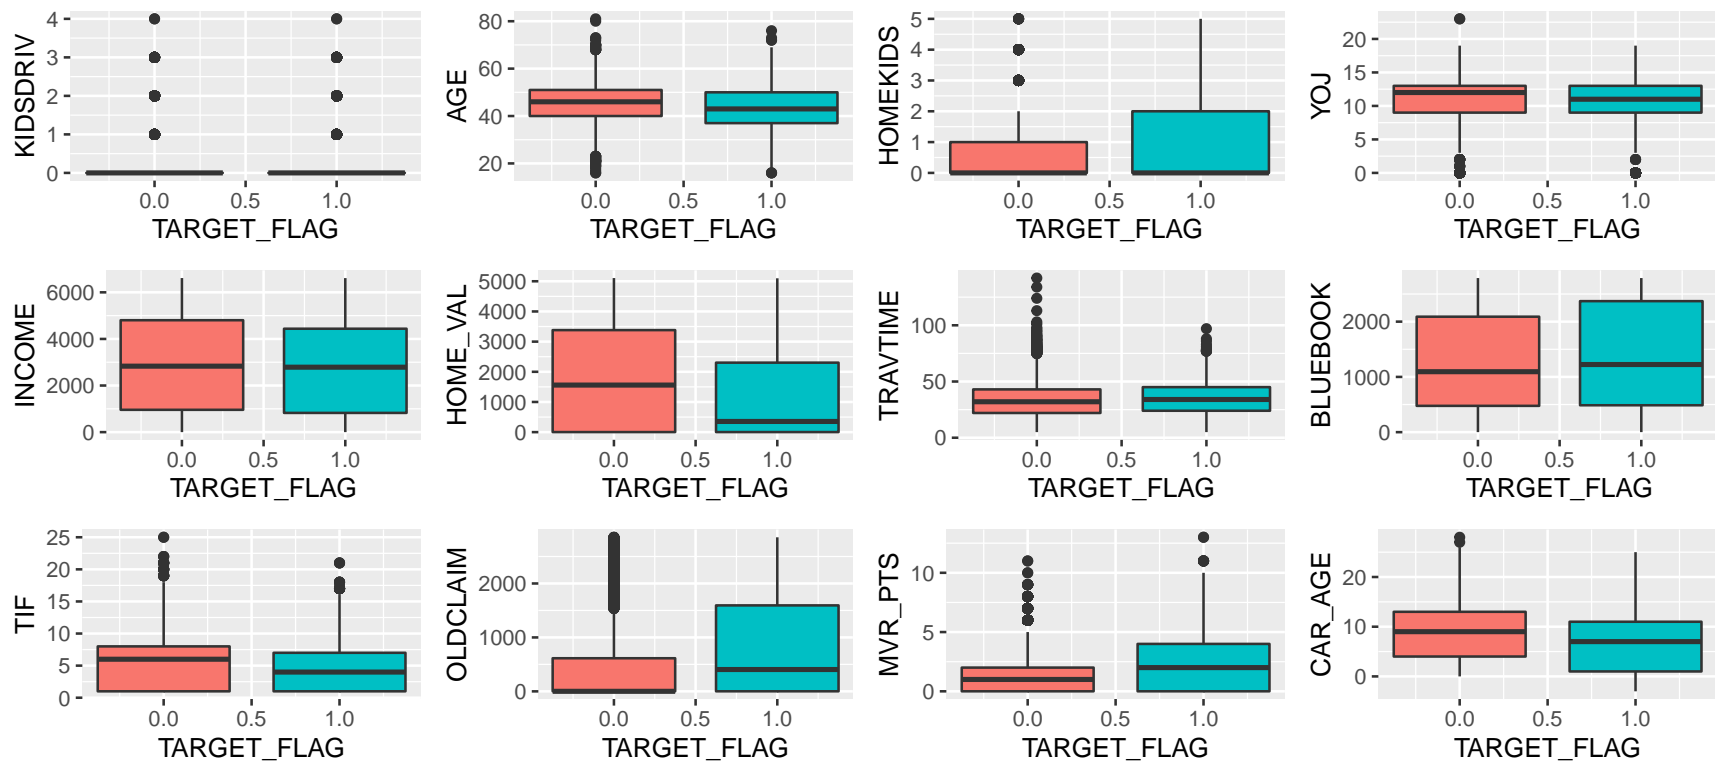

Taking a look at the distributions of numerical variables, the following items observations are revealed:

- Most of the variables are not normally distributed - features will be centered and scaled as part of the preprocessing.
- OLDCLAIM values (past payouts) are mostly 0

Boxplots

For the classification task, it might be insightful to compare distributions of numerical features for the levels of `TARGET_FLAG`. It appears that the features that differ the most between levels of `TARGET_FLAG` are `HOME_VAL`, `OLDCLAIM`, and `MVR_PTS`.

Correlations

Looking at a correlation plot of numeric variables, it is evident that there is some collinearity in the dataset.

- HOMEKIDS AND AGE have a negative correlation
- HOMEKIDS and KIDSDRIV have a positive correlation
- CLM_FREQ AND OLDCLAIM have a strong negative correlation
- MVR_PTS and OLDCLAIM have a negative correlation
- MVR_PTS and CLM_FREQ have a negative correlation

Data Preparation

Based on information gathered by performing exploratory data analysis, we must impute missing values, encode categorical variables, and apply feature transformations.

Missing Values

We will use Multivariable Imputation by Chained Equations (mice) to fill the missing variables.

Encoding

The following categorical features have to be encoded: MSTATUS, HOME_VAL, SEX, EDUCATION, JOB, CAR_USE, RED_CAR, REVOKED, and URBANICITY. To do this, the `dummyVars` function from `caret` will be used.

Taking a look at the new columns in the dataframe, it is clear that some columns are unnecessary. Since each categorical feature requires one less column than categories, we will drop one dummy column for each feature.

Transformations and Output

For the linear regression models, performance will be evaluated using R-squared and RMSE. However, for the binary logistic regression model, performance will also be measured based on test data accuracy. To accomplish this, we will create the following datasets. Train and test sets will be transformed separately.

- insurance_tf: Full dataset, transformed
- insurance_tf_train: 80% split train dataset, transformed
- insurance_tf_test: 20% split test dataset, transformed

Building Models

Reading in cleaned up output dataset:

Multiple Linear Regression

We will try to use all the variables for our initial regression model, to identify which appear to show significance.

```

We can see improvements in R-Squared value after we narrowed the model to highly significant variables. It is however still rather low. Only 7% of the variation in the data can be explained by this model.

We will now use this regression model to predict values for the evaluation data set.

Classification Models

Linear logistic regression

Model 1 - All binary variables with TARGET_FLAG.

Based the fact that the area under the curve for model 2 and model 3 are virtually identical. I am going to select model2 Because Auc value is little bit higher than other.

Further Classification Models

The dataset is imbalanced as we are seeing more number of negative classes than the positive classes.

We will set 0 means “No Car crash” and 1 means “Car crash”

Considering a classifier model like this, by looking at only accuracy may not give a clear picture of model goodness. I’m assuming predicting a case whether a person whether will involve into a car crash is crucial. As we have two types of errors(Type1(False positive) and Type2(False Negative)), we should always avoid both of these error. However in this case, we should focus more on reducing Type2(False Negative). That is predicting Negative when it is really positive so that we loss an opportunity to save a person’s life and as well as claim amounts. We know sensitivity/Recall is a measure of False negative rate. So we will focus on the sensitivity than the precision or accuracy.

Another metrics we will focuss is AUC(Area under curve measure) while comparing different classifiers.

```
##  
##      0      1  
## 4796 1732
```

We will perform 3 classifiers. They are Logistic regression, KNN and Naive Bayes models.

Logistic Regression

```
## Setting levels: control = 0, case = 1  
  
## Setting direction: controls < cases  
  
## Area under the curve: 0.6569
```

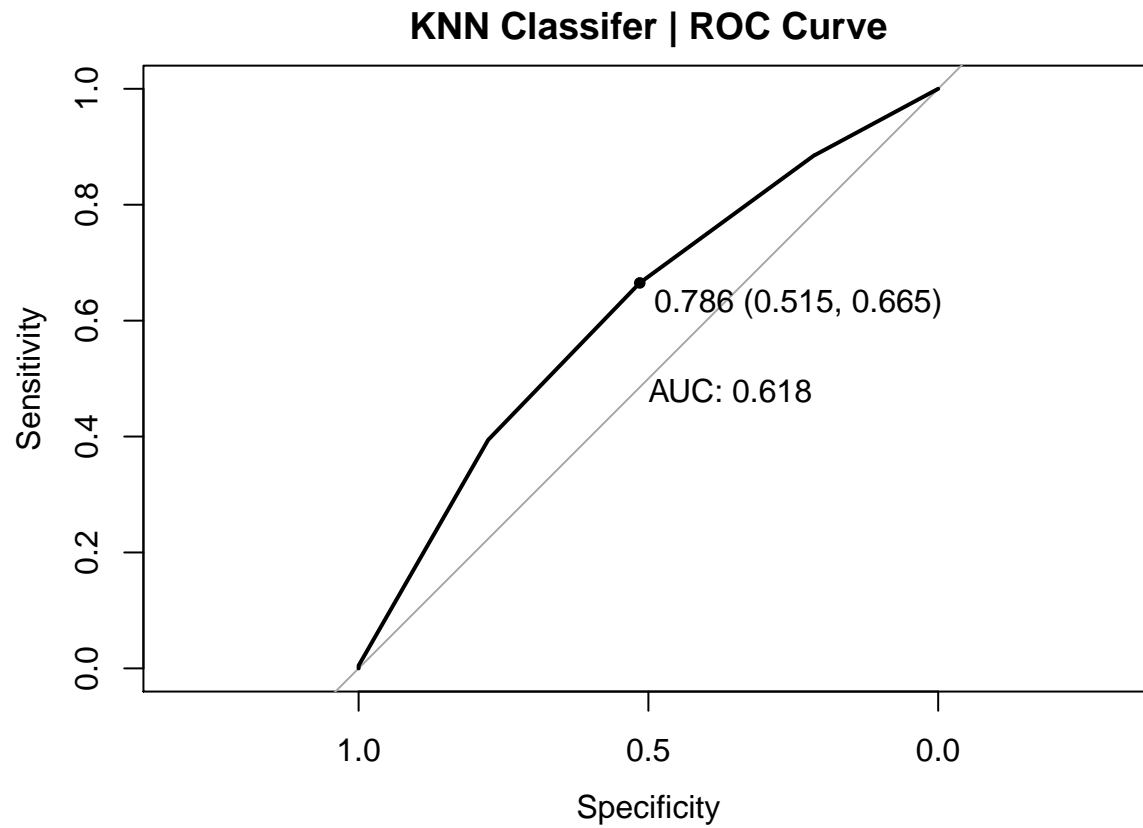

KNN model

```
## Setting levels: control = 0, case = 1
```

```
## Setting direction: controls > cases
```

```
## Area under the curve: 0.618
```

Naive Bayes

```
## Warning: package 'e1071' was built under R version 3.6.1
```

```
## Setting levels: control = 0, case = 1
```

```
## Setting direction: controls < cases
```

```
## Area under the curve: 0.7757
```

Predicting the evaluation dataset

As we are seeing above Naive Bayes gives a better AUC, Sensitivity and Accuracy. Hence we will use naive bayes model to predict the evaluation data set.
